

TOP SECRET MAJIC

SUBJECT: AUTOPSY REPORT # 2

DATE: 7/14/47

COPY ONE OF THREE

INITIAL FINDINGS UPON EXAMINATION
AND AUTOPSY OF THE BODY OF AN
APPARENT ALIEN CREATURE

1. External Appearance

This body was observed to be in a state of profound deterioration. It had not been preserved but was delivered in a container of rubberized canvas, to which some of the tissue had adhered. The cadaver was 36 inches long with a weight of 8 pounds. The external appearance of this cadaver was not of a human type.

The skin appeared smooth and a dark bluish-gray in color. There was no clothing on the body. There were no genitals and no way of determining sex, if any. The nose consisted of two slits, the mouth was a small opening that did not appear to be supported by an articulated jaw, and there were holes in the position of ears. The cranium was round and large in proportion to the body and the eyes were almond-shaped. The eyes were closed and could not be opened without damaging structures, due to condition of decaying tissue.

Arms and wrists were very thin. The hands displayed a three-digit arrangement with-

out thumb. The arms extended to approximately three inches above the knee. The three fingers extended directly from the wrist, with no palm.

2. Dissection

The body was opened from crotch to chin. A green liquid emerged from the incision. The skin was not backed by fascia, and the bone structure appeared to be a cartilaginous substance of light green-blue color.

Internal organs were observed but their function was unclear. The thoracic and peritoneal cavities communicated and there appeared to be no respiratory system and no stomach. The esophagus was vestigial and dissipated before reaching another organ.

There appeared to be two multichambered hearts and it was surmised that body fluid could be pumped rapidly. There was an extensive circulatory system that involved three different types of vein. Some material was extracted from one of these systems and suggested possible waste, leading to the notion that waste may have been exuded through the skin.

The fluid removed from the body was analyzed under the microscope and found to be a vegetable substance, chlorophyll-based. It is possible that photosynthesis was the means of obtaining energy.

The cranium was dissected and it was ob-

served that a ridge of cartilage separated the brain into two completely isolated components. The brain was severely deteriorated, but appeared to be extensively fissured and divided into numerous lobes. Because of the deterioration the degree of bilateralism of the two halves could not be determined with any accuracy.

This cadaver exuded an unusually foul odor.

3. Conclusion

This is not a cadaver of a kind previously observed by or known to this pathologist. It appears to be a form of creature utilizing elements of both the animal and the vegetable.
